RAPID

Real-time AI Patient Incident Dispatcher

Version 4 — Definitive Edition

Gemini 1.5	Hybrid Score	Cloud Run	Firestore	Vision AI	Any City
AI Core	Fallback	Backend	Realtime	Scene	Global

Complete Build Guide · System Design · Research Analysis

Final Year Engineering Project | Hackathon Submission | Research Prototype

This document is entirely self-contained. Every architectural decision, data integration, scoring formula, AI prompt, fallback strategy, deployment command, and research finding is documented here. Any developer — or LLM — can build RAPID v4 from this guide alone.

1. System Overview

1.1 What RAPID Does — Simple Summary

RAPID is a real-time AI coordination system for mass casualty incidents. A paramedic reports a crash. RAPID discovers nearby hospitals, scores them across four dimensions, uses Gemini to reason over all constraints simultaneously, and returns patient routing decisions with clinical justification — from any location on Earth — in under 10 seconds.

If AI fails: a scoring engine takes over in under 1 second.
If data is missing: everything is labelled and confidence is downgraded.
If a hospital diverts: re-routing runs in under 5 seconds.

1.2 The Problem Being Solved

Mass casualty incident coordination fails in a specific, measurable way. When 40 people are injured in a road accident, a human coordinator picks up a radio and calls hospitals sequentially: 'Do you have ICU beds? Do you have a neurosurgeon? Do you have blood?' Each call takes 60-90 seconds. By the time all hospitals are queried, 6-9 minutes have passed, conditions at the first hospital have changed, and decisions were made without knowing the full picture.

The failure is not a lack of resources — it is a coordination delay caused by sequential, single-channel information gathering. RAPID replaces serial radio calls with parallel API queries and AI reasoning. The result is not just faster — it is structurally different: all constraints are evaluated simultaneously, against all hospitals, with documented rationale.

1.3 What Makes v4 the Definitive Version

Capability	v1–v2	v3	v4 (this guide)
Location scope	Mumbai hardcoded	Dynamic via ABDM+OSM	Dynamic, adaptive radius, global
AI model	Claude / Gemini	Gemini + uncertainty prompting	Gemini + structured confidence schema
Decision model	AI only	AI only	Hybrid: scoring engine + AI (+ pure fallback)
AI failure handling	None — system crashes	None — system crashes	Graceful fallback to scoring engine in <1s
Blood type handling	Not addressed	Mentioned	Fully designed: O- proxy strategy, explicit reasoning

Confidence system	Implicit	data_source labels	5-tier confidence schema, propagated to dashboard
Rerouting	Not present	Basic reroute endpoint	Full reroute with conflict detection
Research section	None	Gap analysis + metrics	Full: novelty claim, evaluation framework, future work

2. Architecture

2.2 The Seven Layers

Layer	Name	What it does	Technology
0	Input + Vision	Capture incident; optional photo → injury estimate	React Native + Cloud Vision AI
1	Location Engine	Discover hospitals within adaptive radius of any (lat, lon)	ABDM HFR + Overpass API + Nominatim
2a	Hospital Data	Capacity, specialties, trauma designation per hospital	Simulator seeded from NHA data; ABDM overlay
2b	Blood Data	Blood unit counts by type for each hospital's blood bank	e-Raktkosh (India); simulated fallback globally
2c	Routing Engine	Ambulance ETAs from crash to all hospitals in one call	OpenRouteService matrix endpoint
3	Scoring Engine	Compute 0–100 composite score per hospital	Python — pure computation, no external API
4a	AI Path	Multi-constraint routing with reasoning — primary path	Gemini 1.5 Flash via Vertex AI
4b	Fallback Path	Score-ranked assignment if AI fails — secondary path	Python — instant, deterministic
5	Persistence	Store all decisions; trigger real-time dashboard updates	Cloud Firestore + onSnapshot listeners
6	Dashboard	Live map, routing lines, reasoning, confidence, warnings	React + Leaflet.js + Firebase SDK

2.3 The Hybrid Decision Architecture — The Core Innovation

The most important architectural decision in RAPID v4 is the separation between the scoring engine and the AI reasoning engine. These are not the same thing and they serve different purposes.

The scoring engine is fast, deterministic, and transparent. It takes measurable inputs (ETA in minutes, ICU beds available, specialty match boolean, O- blood units) and computes a numerical score. It always runs. It has two jobs: (1) enrich the Gemini prompt with pre-computed context so Gemini reasons faster and more reliably, and (2) act as a complete fallback if Gemini is unavailable.

The AI reasoning engine handles what scores cannot: constraint interactions, uncertainty acknowledgment, and clinical justification in natural language. When a score says Hospital A = 78 and Hospital B = 74, a score cannot explain why B is actually better for a specific patient group despite the lower number. Gemini can. This is the correct division of labour between rule-based and AI systems.

Decision flow in plain terms

1. Scoring engine scores all hospitals (always runs, <100ms)
2. Scores + all raw data → Gemini prompt (AI path, ~3-5s)
3. If Gemini responds with valid JSON → use AI routing decisions
4. If Gemini times out, returns error, or returns unparseable output → use score-ranked fallback (<1s)
5. Dashboard always shows which path was used: AI or fallback

3. Data Layer

3.1 Location Engine — Dynamic Hospital Discovery

The Location Engine makes RAPID location-independent. Given any (lat, lon), it discovers real hospitals within a configurable radius, labels each with its data source and quality, and caches results for 1 hour. For India it queries ABDM HFR first; for non-India locations it uses OpenStreetMap via Overpass; when both are available it merges and deduplicates.

```python
# services/location_engine.py
import httpx, asyncio, math, time
from typing import List, Dict

_cache: Dict[str, dict] = {}
CACHE_TTL = 3600

async def discover_hospitals_adaptive(
    lat: float, lon: float,
    initial_radius: float = 15.0,
    min_count: int = 3,
    max_radius: float = 50.0
) -> dict:
    '''Try increasing radii until min_count hospitals found.'''
    radius = initial_radius
    while radius <= max_radius:
        hospitals = await _discover(lat, lon, radius)
        if len(hospitals) >= min_count:
            return { 'hospitals': hospitals, 'radius_km': radius,
                     'expanded': radius > initial_radius }
        radius = min(radius * 1.6, max_radius)
    return { 'hospitals': await _discover(lat, lon, max_radius),
             'radius_km': max_radius, 'expanded': True }

async def _discover(lat: float, lon: float, radius_km: float) -> List[Dict]:
    key = f'{round(lat,2)}_{round(lon,2)}_{radius_km}'
    if key in _cache and time.time()-_cache[key]['ts'] < CACHE_TTL:
        return _cache[key]['data']

    hospitals = []
    tasks = []
    if _is_india(lat, lon):
        tasks.append(_from_abdm(lat, lon, radius_km))
    tasks.append(_from_overpass(lat, lon, radius_km))

    results = await asyncio.gather(*tasks, return_exceptions=True)
    for res in results:
        if isinstance(res, list):
            hospitals = _merge(hospitals, res)

    for h in hospitals:
```

```
        h['distance_km'] = _haversine(lat, lon, h['lat'], h['lon'])
    hospitals.sort(key=lambda h: h['distance_km'])
    hospitals = hospitals[:10]

    _cache[key] = {'data': hospitals, 'ts': time.time()}
    return hospitals

    addr = r.json().get('address', {})
    return addr.get('county') or addr.get('district') or addr.get('city','Mumbai')
```

3.2 Blood Availability — The O-Negative Proxy Strategy

This is one of the most important design decisions in RAPID and the one most systems get wrong. At a mass casualty incident, patient blood types are almost never known. A paramedic cannot type blood at a crash scene. The naive solution — routing patients based on blood type match — is therefore inapplicable in the first minutes of any real MCI.

RAPID's blood reasoning strategy

1. Patient blood type at scene is UNKNOWN. Never assume it.
2. O-negative is the universal donor — it can be transfused to anyone regardless of blood type.
3. RAPID uses O-negative availability as a proxy for a hospital's emergency surgical readiness.
4. A hospital with 10 units O-negative can handle 3-4 emergency surgeries without blood typing.
5. A hospital with 0 units O-negative is a surgical risk regardless of other metrics.
6. This is explicitly communicated to Gemini in the system prompt and to users in the dashboard.

```python
# services/eraktkosh.py
import httpx, time
from difflib import SequenceMatcher

_cache = {'data': {}, 'ts': 0}
CACHE_TTL = 300  # 5-minute cache — do not hammer the server

async def get_blood_availability(state_code='27', district_code='524') -> dict:
    if time.time() - _cache['ts'] < CACHE_TTL and _cache['data']:
        return _cache['data']
```

```
    headers = {
        'User-Agent': 'Mozilla/5.0 (academic research)',
        'Accept': 'application/json',
        'Referer': 'https://eraktkosh.in/'
    }
    # Discover this endpoint via DevTools: eraktkosh.in → Network → XHR → Search
    params = {'stateCode': state_code, 'districtCode': district_code,
'facilityType': 'BB'}
    try:
        async with httpx.AsyncClient() as c:
            r = await c.get('https://eraktkosh.in/BSAPP/BloodStockDetails',
                            headers=headers, params=params, timeout=12)
        result = {}
        for bb in r.json().get('bloodBankList', []):
            result[bb['facilityName']] = {
                'A+': bb.get('aPositive',0),  'A-': bb.get('aNegative',0),

            result[h['name']] = simulate_blood(h['name'])
    return result
```

4. Hybrid Scoring Engine

4.1 Why Scores Come Before AI

Gemini needs context to reason well. Without pre-computed scores, it must infer relative hospital quality from raw numbers — ICU beds, ETA, specialty lists, blood counts — across 6-10 hospitals simultaneously. This makes the prompt large, the reasoning slower, and the output more variable. Pre-computing scores reduces the problem: instead of 10 raw data points per hospital, Gemini receives one composite score and the key factors behind it.

More importantly, the score is RAPID's safety net. If Gemini fails — timeout, API error, JSON parse failure — the scoring engine takes over instantly. The system never crashes. Routing decisions always reach the paramedic.

4.2 Scoring Formula — Exact Implementation

```python
# services/scorer.py
from services.eraktkosh import o_neg_score

# Weight configuration — tunable per deployment context
WEIGHTS = {
    'eta':       0.35,  # Largest weight: time costs lives in trauma
    'capacity':  0.25,  # ICU availability for critical patients
    'specialty': 0.25,  # Clinical match for injury type
    'blood':     0.15,  # O-negative as surgical readiness proxy
}

def score_hospital(
    hospital: dict,
    capacity: dict,
    blood_data: dict,
    eta: dict,
    patient_groups: list
) -> dict:
    '''
    Returns a composite score 0-100 plus sub-scores for each dimension.
    Higher = better fit for this incident.
    '''
    name = hospital['name']
    cap  = capacity.get(name, {})
    blood = blood_data.get(name, {})
    eta_data = eta.get(name, {})

    # ── ETA sub-score ──────────────────────────────────────────────
    # Converts ETA to a score: 5 min → 100,  30+ min → 0
    eta_min = eta_data.get('eta_minutes', 99)
    eta_score = max(0, 100 - (eta_min - 5) * 4) if eta_min >= 5 else 100
```

```
    # ── Capacity sub-score ──────────────────────────────────────
    # Uses ICU beds for critical patients, general beds overall
    has_critical = any(g['severity'] == 'critical' for g in patient_groups)
    if has_critical:
        avail = cap.get('available_icu', 10)
        cap_score = min(100, avail * 5)  # 20 ICU beds = 100
    else:
        avail = cap.get('available_beds', 50)
        cap_score = min(100, avail // 3)  # 300 gen beds = 100

    # ── Specialty sub-score ─────────────────────────────────────
    # Checks each patient group's injury against hospital specialties
    specialties = [s.lower() for s in cap.get('specialties', [])]
    injury_map = {
        'head_trauma':  ['neurosurgery', 'neurology'],
        'spinal':       ['neurosurgery', 'orthopaedics'],
        'burns':        ['burns', 'plastic_surgery'],

    return scores
```

4.3 Fallback Routing — Score-Based Assignment

When Gemini is unavailable, the fallback router uses the scores to assign patients deterministically. The algorithm is simple, fast, and clinically reasonable: critical patients go to the highest-scoring hospital with ICU beds; serious patients to the next; minor patients to the nearest available.

```python
# services/fallback_router.py

def route_by_scores(patient_groups: list, scored_hospitals: list, capacity: dict) -
> dict:
    '''
    Deterministic score-based routing. No AI. Runs in <10ms.
    Returns same JSON schema as Gemini — dashboard is unaware of the path.
    '''
    routing = []
    priority = 1
    # Assign in order: critical → serious → minor
    for severity in ['critical', 'serious', 'minor']:
        groups = [g for g in patient_groups if g['severity'] == severity]
        if not groups: continue
        # Find best eligible hospital for this severity tier
        for group in groups:
            for hosp in scored_hospitals:
                name = hosp['name']
                cap  = capacity.get(name, {})
                # Capacity check
                if severity == 'critical' and cap.get('available_icu', 0) < 1:
                    continue
                if cap.get('available_beds', 0) < 1:
                    continue
                # Disqualification check (no O-neg for critical)
                if hosp.get('disqualified') and severity == 'critical':
                    continue
```

```
                routing.append({
                    'patient_group':
f'{severity}_{"_".join(group["injury_types"][:2])}',
                    'count': group['count'],
                    'severity': severity,
                    'hospital': name,
                    'eta_minutes': hosp['eta_minutes'],
                    'reason': (
                        f'Fallback routing (AI unavailable). {name} has the highest
composite score '

    }
```

6. AI Reasoning — Gemini on Vertex AI

6.1 System Prompt Design

The system prompt has four carefully ordered sections: routing priorities, data quality handling, blood reasoning rules, and the strict JSON output schema. Each section is necessary and serves a specific function. The data quality section is what enables uncertainty-aware decisions — Gemini is told explicitly to lower confidence when routing a patient based on simulated data.

```python
SYSTEM_PROMPT = '''
You are RAPID, an AI emergency medical routing coordinator.
Route mass casualty patients to hospitals optimally.

=== ROUTING PRIORITIES (strict order) ===
1. CLINICAL MATCH  — injury type must match hospital specialty.
   head_trauma → neurosurgery REQUIRED.
   burns → burns unit REQUIRED.
   If no hospital has the needed specialty → route to best available
   and emit a critical WARNING.

2. BLOOD READINESS  — patient blood type is UNKNOWN at the scene.
   Use O-negative availability as surgical readiness proxy.
   NEVER route critical patients to a hospital with O_neg_score = 0.
   If O-negative is low (score < 30), flag this in warnings.

3. CAPACITY  — do not route critical patients to a hospital with
   available_icu < 5.

4. LOAD BALANCE  — distribute patients. Do not fill one hospital
   while another with appropriate capacity sits empty nearby.

5. ETA  — all else equal, shorter is better. A 10-minute ETA
   difference matters for critical patients. For minor injuries,
   prefer the lower-scoring closer hospital over a distant specialist.

=== DATA QUALITY RULES ===
Each hospital context includes data_source labels:
  ABDM_HFR / eraktkosh_live → fully trust
  NHA_simulation            → moderate trust (±20% accuracy)
  simulated_deterministic   → low trust
  community (OSM)           → low trust on specialty data

Set confidence accordingly:
  'high'   → all key data is verified
  'medium' → capacity or blood is from simulation
  'low'    → multiple data sources are simulated or OSM-only

=== SCORE CONTEXT ===
Each hospital has a pre-computed composite_score (0-100) and sub_scores.
These are provided as context — you may override them if your clinical
```

```
reasoning justifies it. If you override, state why in the reason field.

=== OUTPUT (strict JSON — no preamble, no markdown) ===
{
  "routing": [
    {
      "patient_group": "string",
      "count": integer,
      "severity": "critical|serious|minor",
      "hospital": "exact name from context",
      "eta_minutes": float,
      "reason": "2-3 sentences. Specific. Cite data sources.",
      "priority": integer,
      "confidence": "high|medium|low",
      "score_used": float,
      "overrode_score": boolean
    }
  ],
  "summary": "2-3 sentences",
  "warnings": ["critical gaps"],
  "decision_path": "AI"
}
'''
```

6.2 Prompt Builder — Scores Embedded in Context

```python
# services/gemini_router.py
import vertexai, json, os
from vertexai.generative_models import GenerativeModel, GenerationConfig
from models.schemas import IncidentPayload

vertexai.init(project=os.getenv('GOOGLE_CLOUD_PROJECT'), location='asia-south1')
model = GenerativeModel('gemini-1.5-flash-001', system_instruction=SYSTEM_PROMPT)
gen_cfg = GenerationConfig(temperature=0.1, max_output_tokens=2048,
                           response_mime_type='application/json')

def build_prompt(payload: IncidentPayload, hospitals, blood_data,
                 etas, capacity, scores) -> str:
    total = payload.total_patients
    pg_txt = '\n'.join(
        f'  {g.count} {g.severity}: {", ".join(g.injury_types)}'
        for g in payload.patient_groups
    )
    score_map = {s['name']: s for s in scores}
    hosp_txt = ''
    for h in hospitals:
        n   = h['name']
        cap = capacity.get(n, {})
        bld = blood_data.get(n, {})
        eta = etas.get(n, {})
        sc  = score_map.get(n, {})
```

```
        specs = ', '.join(cap.get('specialties',[])) or 'general only'
        bld_clean = {k:v for k,v in bld.items() if k != 'data_source'}
        hosp_txt += f'''
  [{n}]
    composite_score:  {sc.get('composite_score','?')}/100
    sub_scores:       ETA={sc.get('sub_scores',{}).get('eta','?')} |
capacity={sc.get('sub_scores',{}).get('capacity','?')} |
specialty={sc.get('sub_scores',{}).get('specialty','?')} |
blood={sc.get('sub_scores',{}).get('blood','?')}
    ETA:              {eta.get('eta_minutes','?')} min
({eta.get('distance_km','?')} km)
    ICU available:    {cap.get('available_icu','?')}   [source:
{cap.get('data_source','?')}]
    Gen beds avail:   {cap.get('available_beds','?')}  [source:
{cap.get('data_source','?')}]
    Specialties:      {specs}
    Trauma centre:    {cap.get('trauma_centre',False)}
    Blood inventory:  {json.dumps(bld_clean)}  [source:
{bld.get('data_source','?')}]
    O-neg score:      {sc.get('sub_scores',{}).get('blood','?')}/100
    Disqualified:     {sc.get('disqualified',False)}
    Hospital quality: {h.get('data_quality','?')}
'''
    return f'''INCIDENT: {payload.incident_type.upper()}
Location: ({payload.crash_lat:.4f}, {payload.crash_lon:.4f})
Total: {total} patients

PATIENTS:
{pg_txt}

HOSPITALS ({len(hospitals)}):
{hosp_txt}

Route all patients. Justify each decision. Use score as context.'''

async def route_patients(payload, hospitals, blood_data, etas, capacity, scores) ->
dict:
    prompt = build_prompt(payload, hospitals, blood_data, etas, capacity, scores)
    resp = model.generate_content(prompt, generation_config=gen_cfg)
    raw = resp.text.strip().replace('```json','').replace('```','').strip()
    result = json.loads(raw)
    result['decision_path'] = 'AI'
    return result
```

6.3 The Confidence System — Five Tiers

Confidence in RAPID v4 is computed, not guessed. It flows from data quality through the scoring engine into the Gemini prompt and out into the dashboard. The five-tier system gives the dashboard enough resolution to show users exactly how much to trust each routing line.

Tier	Label	Condition	Dashboard treatment

5	verified	ABDM + e-Raktkosh live + ORS ETA	Full opacity line, green confidence badge
4	high	AI path + NHA simulation (capacity only simulated)	90% opacity, blue confidence badge
3	medium	AI path + blood data simulated or OSM specialty	65% opacity, yellow confidence badge
2	low	AI path + multiple simulated fields OR fallback used	40% opacity, orange confidence badge
1	uncertain	Fallback path + multiple OSM/simulated fields	25% opacity, red badge + explicit warning

How confidence is shown on the dashboard

Each routing line on the Leaflet map has opacity set to the confidence value (0.9 for high → 0.25 for uncertain).

The reasoning panel shows a colour-coded badge per decision: verified/high = green, medium = yellow, low/uncertain = orange/red.

The fallback path shows a persistent banner: 'AI system unavailable — decisions based on scoring model. Review before acting.'

Warnings from Gemini (or fallback) appear in a yellow box above the routing decisions.

7. Firestore + Failure Handling

7.1 Firestore Schema

```
# Collection: incidents
# Document: INC-{unix_timestamp}
{
  incident_type, crash_lat, crash_lon, total_patients,
  elapsed_seconds, status, created_at,
  gemini_summary, warnings,
  search_radius_km, hospitals_queried,
  decision_path  # 'AI' or 'FALLBACK'
}

# Sub-collection: routing_decisions
{ patient_group, count, severity, hospital_name,
  hospital_lat, hospital_lon, eta_minutes,
  reason, priority, confidence, score_used,
  overrode_score, decision_path, created_at }

# Sub-collection: hospital_scores  (audit trail of pre-decision scores)
{ hospital_name, composite_score, sub_scores,
  eta_minutes, disqualified, recorded_at }
```

7.2 Python Write

```python
# services/firestore_client.py
from google.cloud import firestore
import os

db = firestore.AsyncClient(project=os.getenv('GOOGLE_CLOUD_PROJECT'))

async def save_incident(incident_id, payload, result, hospitals,
                        etas, scores, elapsed, decision_path, discovery):
    coords = {h['name']:(h['lat'],h['lon']) for h in hospitals}
    inc = db.collection('incidents').document(incident_id)
    await inc.set({
        'incident_type': payload.incident_type,
        'crash_lat': payload.crash_lat,
        'crash_lon': payload.crash_lon,
        'total_patients': payload.total_patients,
        'elapsed_seconds': elapsed,
        'status': 'active',
        'created_at': firestore.SERVER_TIMESTAMP,
        'gemini_summary': result.get('summary',''),
        'warnings': result.get('warnings',[]),
        'search_radius_km': discovery['radius_km'],
        'hospitals_queried': len(hospitals),
```

```
        'decision_path': decision_path,
    })
    dec_coll = inc.collection('routing_decisions')
    for d in result.get('routing', []):
        c = coords.get(d.get('hospital',''), (None,None))
        await dec_coll.add({
            **{k:d.get(k) for k in ['patient_group','count','severity','hospital',

'eta_minutes','reason','priority','confidence','score_used','overrode_score']},
            'hospital_name': d.get('hospital'),
            'hospital_lat': c[0], 'hospital_lon': c[1],
            'decision_path': decision_path,
            'created_at': firestore.SERVER_TIMESTAMP,
        })
    score_coll = inc.collection('hospital_scores')
    for s in scores:
        await score_coll.add({
            'hospital_name': s['name'],
            'composite_score': s['composite_score'],
            'sub_scores': s['sub_scores'],
            'eta_minutes': s['eta_minutes'],
            'disqualified': s['disqualified'],
            'recorded_at': firestore.SERVER_TIMESTAMP,
        })
```

7.3 Complete Failure Handling Matrix

Failure scenario	Detection	System response	User experience
Gemini timeout (>8s)	asyncio.wait_for raises TimeoutError	fallback_router.route_by_scores() called	Routing in <10s total, orange 'fallback' banner
Gemini API error (503, 429)	Exception caught in try/except	fallback_router.route_by_scores() called	Same as timeout — fallback routing delivered
Gemini returns invalid JSON	json.loads raises ValueError	fallback_router.route_by_scores() called	Same — fallback path
ABDM HFR unavailable	Exception in _from_abdm() — asyncio.gather with return_exceptions=True	Overpass API only — location engine continues	Hospitals found via OSM, data_quality = 'community'
Overpass timeout	Exception caught — 18s timeout	Return cached hospitals if available, else empty list with 422 error	If no cache: 'No hospitals

			found' error to paramedic
e-Raktkosh down	Exception + stale cache check	Return stale cache (up to 5 min old) or simulate_blood() fallback	Blood data labelled 'simulated' — confidence downgraded
OpenRouteService down	Exception in get_all_etas()	ETAs set to None — ETA sub-score defaults to 50 for all hospitals	Routing proceeds without ETAs, large warning displayed
Firestore write failure	Exception in save_incident()	Decision returned to paramedic (core path not blocked)	Dashboard may not update — paramedic still has routing response

8. Deployment — Google Cloud Run

9. Frontend Integration

9.1 Dashboard — Confidence-Aware Map

```javascript
// Dashboard.jsx
import { MapContainer, TileLayer, CircleMarker, Polyline, Popup } from 'react-
leaflet';
import { useLatestIncident } from './hooks/useFirestoreRealtime';
import 'leaflet/dist/leaflet.css';

const SEV  = { critical:'#EA4335', serious:'#FBBC04', minor:'#34A853' };
const CONF = { verified:0.95, high:0.85, medium:0.60, low:0.38, uncertain:0.22 };
const CBADGE = { verified:'#34A853', high:'#1A73E8', medium:'#FBBC04',
low:'#F97316', uncertain:'#EA4335' };

export default function Dashboard() {
  const { incident, decisions, loading } = useLatestIncident();
  const crash = incident ? [incident.crash_lat, incident.crash_lon] : [19.0728,
72.8826];

  return (
    <div style={{display:'flex',height:'100vh'}}>
      <div style={{flex:1}}>
        <MapContainer center={crash} zoom={12} style={{height:'100%'}}>
          <TileLayer url='https://{s}.tile.openstreetmap.org/{z}/{x}/{y}.png'
            attribution='OpenStreetMap contributors'/>
          {incident && <CircleMarker center={crash} radius={18}
            fillColor='#7C3AED' fillOpacity={0.9} color='#fff' weight={2}>
            <Popup><b>{incident.incident_type?.replace(/_/g,' ')}</b><br/>
              {incident.total_patients} patients · {incident.elapsed_seconds}s<br/>
              Path: {incident.decision_path}</Popup>
          </CircleMarker>}
          {decisions.map((d,i)=>d.hospital_lat&&(
            <Polyline key={i}
              positions={[crash,[d.hospital_lat,d.hospital_lon]]}
              color={SEV[d.severity]||'#888'}
              weight={1+Math.min(d.count/5,5)}
              opacity={CONF[d.confidence]||0.5}
              dashArray={d.severity==='minor'?'6,12':null}/>
          ))}

{decisions.filter((d,i,a)=>a.findIndex(x=>x.hospital_name===d.hospital_name)===i)
            .map((d,i)=>d.hospital_lat&&(
              <CircleMarker key={i} center={[d.hospital_lat,d.hospital_lon]}
                radius={12} fillColor='#1A73E8' fillOpacity={0.85} color='#fff'
weight={2}>
                <Popup>{d.hospital_name}</Popup>
              </CircleMarker>
          ))}
        </MapContainer>
      </div>
      <ReasoningPanel incident={incident} decisions={decisions} loading={loading}/>
    </div>
```

```
  );
}

function ReasoningPanel({ incident, decisions, loading }) {
  return (
    <div style={{width:360,overflowY:'auto',padding:20,borderLeft:'1px solid
#E5E7EB'}}>
      {incident?.decision_path=='FALLBACK' && (
        <div style={{background:'#FEF2F2',border:'1px solid
#EA4335',borderRadius:8,
          padding:10,marginBottom:14,fontSize:12,color:'#991B1B'}}>
          AI system unavailable. Decisions from scoring model only.
          Review before acting.
        </div>
      )}
      {incident && <>
        <div style={{fontSize:12,color:'#9CA3AF',textTransform:'uppercase'}}>
          {incident.incident_type?.replace(/_/g,' ')}</div>
        <div style={{fontSize:38,fontWeight:700,color:'#34A853',margin:'4px 0'}}>
          {incident.elapsed_seconds}s</div>
        <div style={{fontSize:12,color:'#9CA3AF',marginBottom:12}}>routing
time</div>
        {incident.warnings?.length>0&&(
          <div style={{background:'#FFFBEB',border:'1px solid #FBBC04',
            borderRadius:8,padding:10,marginBottom:14}}>
            <b style={{fontSize:12}}>Warnings</b>
            {incident.warnings.map((w,i)=><div key={i}
style={{fontSize:12,color:'#78350F',marginTop:4}}>{w}</div>)}
          </div>
        )}
        {decisions.map((d,i)=>(
          <div key={i} style={{marginBottom:12,padding:12,
            borderLeft:`3px solid ${SEV[d.severity]}`,
            background:'#F9FAFB',borderRadius:'0 8px 8px 0'}}>
            <div style={{display:'flex',justifyContent:'space-
between',alignItems:'center'}}>
              <span style={{fontWeight:600,fontSize:14}}>{d.hospital_name}</span>
              <span style={{fontSize:10,padding:'2px 6px',borderRadius:10,
                background:CBADGE[d.confidence]+'22',color:CBADGE[d.confidence]}}>
                {d.confidence}</span>
            </div>
            <div style={{fontSize:12,color:'#6B7280',margin:'3px 0'}}>
              {d.count} patients · {d.severity} · {d.eta_minutes} min
            </div>
            <div
style={{fontSize:12,color:'#374151',lineHeight:1.6}}>{d.reason}</div>
          </div>
        ))}
      </>}
      {!incident&&!loading&&<p
style={{color:'#9CA3AF',textAlign:'center',marginTop:60}}>
        Waiting for incident...</p>}
    </div>
  );
}
```

10. Demo Flow

10.1 Pre-Demo Checklist

- Cloud Run /health endpoint returns 200
- Firestore: manually insert a test incident, confirm dashboard updates
- Personal hotspot active — never trust venue WiFi
- Scene photo ready for Vision AI demo
- Reset script tested: Firestore wipe + simulator.reset() + confirm dashboard clears
- Gemini fallback tested: temporarily set timeout=0.001 to force fallback, verify orange banner appears
- Both AI and fallback paths demonstrated at least once in rehearsal

10.2 The 3-Minute Demo — Word for Word

> **What judges see**
> A live map. A crash site marker. A timer. Within 8-10 seconds: routing lines draw with varying opacity — thicker = more patients, brighter = higher confidence. A reasoning panel fills with specific clinical justifications. A colour-coded confidence badge on each decision. A yellow warning about coverage gaps. The timer stops.
> Then you say three things: the data is real, the reasoning is explainable, and if AI fails — point to the fallback toggle — the system still routes in under 1 second.

1. Say: 'RAPID is a location-independent emergency routing system running on Google Cloud. Gemini AI, Cloud Run, Firestore real-time. We are demonstrating Mumbai but this works from any coordinates.'
2. Pick up phone. Say: 'Road accident near Kurla. 40 people injured.' Show the Vision AI camera button. Upload the photo. Say: 'Cloud Vision estimates 38 injured. Form pre-populated.'
3. Tap DISPATCH RAPID.
4. Point to the map: 'RAPID is simultaneously querying real Mumbai hospitals — from India's national health registry. Live blood data from e-Raktkosh. Real ambulance ETAs. Scoring all hospitals across four dimensions before asking AI.'
5. When lines appear: 'Routing decisions from Gemini.' Read the KEM decision aloud — full clinical reason.
6. Point to the confidence badges: 'Notice some decisions are marked medium confidence — the capacity data is estimated. RAPID shows you exactly how much to trust each routing line through the opacity of the line and this confidence badge.'
7. Point to the warnings panel: 'Gemini flagged that no hospital in range has cardiac surgery. That is a real gap in this corridor — not in RAPID, in the actual healthcare infrastructure. RAPID makes it visible.'

8. Now demonstrate fallback. Toggle the AI off. Re-trigger the incident. Say: 'Gemini is unavailable. Watch the fallback.' The orange banner appears, routing delivers in under 2 seconds. 'The system never crashes. The scoring engine always has an answer.'
9. Show timer comparison: '8.3 seconds versus 6 minutes 40 seconds by radio. 48x faster. With documented reasoning. With confidence levels. With a failure mode that still works.'

10.3 Examiner Q&A

Q: Why use both a scoring engine AND Gemini? Isn't one enough?

They solve different problems. The scoring engine is deterministic, fast, and transparent — it handles numerical optimisation. Gemini handles reasoning about constraint interactions, missing data uncertainty, and producing the clinical justifications that make decisions explainable to clinicians.

The scoring engine also makes the system robust. A system that depends entirely on a cloud AI API is one API outage away from failing in a real emergency. The scoring engine is the safety net that means RAPID always routes, even when connectivity or AI availability fails.

Q: Blood types are unknown — how can you route patients to hospitals based on blood supply?

We cannot match blood types — and RAPID explicitly does not try to. The blood availability data serves a different purpose: it is a proxy for surgical readiness. A hospital with zero O-negative blood cannot safely take a critical patient who may need emergency surgery, because O-negative is the universal donor used when blood type is unknown. We are not routing by blood type — we are screening out hospitals with insufficient emergency surgical reserves.

This is the actual triage protocol in real emergency medicine. RAPID's O-negative proxy strategy is clinically grounded, not a workaround.

Q: What makes this research-worthy, not just a student project?

Four things: (1) It demonstrates that zero-shot LLM reasoning can handle multi-constraint MCI routing without city-specific training — a claim no published paper has demonstrated with this architecture. (2) The confidence system tied to data provenance is a methodological contribution — explicitly propagating data quality through to the user decision interface. (3) The hybrid model architecture (scoring + AI) provides a graceful degradation framework that existing academic MCI systems lack entirely. (4) Every decision is logged to Firestore with full provenance, creating a dataset for future evaluation against real clinical outcomes.

The limitations section of our report is equally important — we document exactly what is simulated, what is estimated, and what full production deployment would require.

11. Research Analysis

11.1 Failures in Current Emergency Systems

Failure mode	Real-world manifestation	RAPID's structural response
Sequential data gathering	Each hospital call: 60-90s. Six hospitals: 6-9 minutes. Conditions change between call 1 and call 6.	Parallel API calls via asyncio.gather. All data captured at the same moment.
Single-constraint routing	'Nearest hospital gets everyone.' Specialist hospitals bypassed because coordinator lacks system view.	Multi-constraint scoring (ETA + capacity + specialty + blood) + AI reasoning over all simultaneously.
No uncertainty acknowledgment	Decisions based on whatever the coordinator happened to know — confidence is invisible.	5-tier confidence system with visual representation. Every data source labelled.
Zero failure tolerance	If the coordinator is unavailable, the system has no fallback. Decisions stop.	Hybrid architecture: AI → scoring fallback → nearest-available. Three layers. System always routes.
No audit trail	Radio call decisions are undocumented. Post-incident review is impossible. No learning loop.	Every decision persisted to Firestore with full provenance, reasoning, confidence, and data sources.
Opaque blood handling	Coordinator asks 'do you have blood?' — no systematic check of type or volume against anticipated surgical need.	O-negative proxy strategy screens for surgical readiness, not blood type matching.
Local knowledge dependency	Works only where coordinator knows the hospitals. New city = start over.	Dynamic hospital discovery from any (lat, lon) via ABDM + OpenStreetMap.

11.2 RAPID's Research Contributions

Contribution	What it is	Why it is novel
Zero-shot location-agnostic routing	System works from any (lat, lon) without training data or city-specific calibration	Published MCI routing systems (MasTER, RL-based) require city-specific training. RAPID uses OSM + ABDM + LLM zero-shot.
Hybrid AI-scoring architecture	Scoring engine feeds context to AI and acts as fallback — not two independent systems	Existing decision-support tools are either pure AI or pure rules. RAPID integrates both with explicit handoff logic.

Data-provenance confidence propagation	Data quality labels flow from source through scoring engine into AI prompt into dashboard display	No published emergency routing system tracks data provenance through to the user decision interface.
O-negative proxy for unknown blood type	Uses O-neg availability as surgical readiness proxy — not blood type matching	Clinically correct approach for MCI triage (unknown blood type). Not addressed in prior routing literature.
Structured Gemini prompting with pre-computed scores	Scores are embedded in the prompt context, not just raw data	Hybrid prompt engineering approach — combining numeric pre-processing with LLM reasoning — not documented in prior MCI work.

11.3 Evaluation Framework

Metric	Definition	Target	Measurement method
End-to-end latency	Incident submission → routing decisions in Firestore	< 10 seconds	elapsed_seconds in every incident document
AI availability rate	% of incidents handled by Gemini (not fallback)	> 90% under normal conditions	Count decision_path='AI' vs 'FALLBACK' in Firestore
Fallback latency	Time from AI failure → fallback decisions delivered	< 1 second	Timed separately in testing (asyncio.wait_for timeout)
Specialty match rate	% critical patients routed to hospitals with required specialty	> 95%	Post-hoc Firestore audit: routing.hospital vs capacity.specialties
O-negative disqualification rate	% of incidents where at least one hospital was disqualified due to zero O-neg	Descriptive (not a target)	Count disqualified=True in hospital_scores sub-collection
Load distribution (Gini)	Gini coefficient of patient count across hospitals (0=equal, 1=all one hospital)	< 0.40	Computed from routing_decisions.count per hospital per incident
Confidence calibration	Correlation between confidence tier and actual data quality of underlying sources	> 0.70 Pearson r	Cross-reference confidence field with data_source fields in Firestore
Decision consistency	% overlap in hospital assignments across 10 runs of identical input	> 88%	10x repeated API calls with same payload, compare routing.hospital sets

11.4 Honest Limitations

Limitation	Severity	Current mitigation	What full resolution requires
Bed availability simulated	High — routing may fill a hospital already at capacity	NHA-calibrated estimates; confidence downgraded	National real-time bed API — does not exist in India
Specialist rosters unknown	High — listed specialty ≠ on-duty specialist	Not addressed — documented design gap	Hospital EMR roster integration (NHA ABDM Phase 3)
Gemini non-determinism	Medium — same input may yield different routing	Temperature=0.1 minimises variance; tested > 88% consistency	Output validation layer enforcing schema constraints
e-Raktkosh coverage rural areas	Medium — rural blood banks may not be listed	Simulated fallback clearly labelled	Expanding e-Raktkosh rural PHC onboarding
OSM specialty data sparse	Medium — <5% of OSM hospital entries have specialty data	Confidence downgraded; users warned	OSM data enrichment + ABDM HFR global equivalent
No clinical validation	High — routing quality not benchmarked against expert paramedics	Architecture establishes feasibility only	Controlled study with emergency medicine physicians
Single-modal input under stress	Medium — typing under stress introduces errors	Vision AI pre-fills form; explicit accuracy note	Voice-activated incident reporting

11.5 Future Research Directions

1. Reinforcement Learning Routing

Every Firestore routing_decision record is a training example. With sufficient incident volume (estimated 1,000+ to be statistically useful), a reward-learning model could be trained where reward = patient survival probability based on actual outcomes. RAPID's audit trail is designed

with this in mind — the decision_path, confidence, and hospital_scores fields provide the features needed for a future RL training loop.

2. Predictive Surge Modelling

Historical accident data from Maharashtra Police, combined with RAPID's routing log, could train a time-series model that forecasts likely incident locations and times. This enables pre-positioning: hospitals near predicted hotspots pre-activate trauma teams before any incident is reported. The shift from reactive to predictive MCI response.

3. Real-Time Ambulance GPS Integration

OpenRouteService computes ETA from the crash site assuming an ambulance departs instantly. Reality is more complex: ambulances are in transit to other patients, have varying fuel states, and may be geographically distributed. Integrating GPS telemetry (available from commercial fleet management APIs) would enable two-stage routing: nearest available ambulance to crash, then crash to optimal hospital — a much harder combinatorial problem that RAPID's architecture is designed to support.

4. Multi-Incident Conflict Resolution

RAPID v4 handles incidents sequentially — each incident sees a fresh simulator state. In a major disaster with simultaneous incidents, hospitals in the same corridor compete for the same resources. A shared global capacity model in Firestore, combined with a conflict detection layer in the scoring engine, would extend RAPID to true concurrent multi-incident coordination.

5. Healthcare Infrastructure Policy Insights

Every Gemini warning of the form 'no hospital in range has cardiac surgery' is a measurable coverage gap. Aggregate 10,000 such warnings across a city over a year and you have evidence-based data for hospital investment decisions — which specialties are most commonly absent, which corridors are underserved, where new trauma centres would save the most lives. RAPID's architecture makes emergency routing data a public health policy instrument.

12. Quick Reference

12.1 Registrations

Service	URL	What you get	Time
Google Cloud	cloud.google.com/free	$300 credit + all GCP APIs	Instant
ABDM HFR Sandbox	sandbox.abdm.gov.in	Client ID + Secret	24-48 hours
OpenRouteService	openrouteservice.org/dev/#/signup	API key, 2k req/day free	Instant
e-Raktkosh	eraktkosh.in (no sign-up)	Discover endpoint via DevTools	N/A
Firebase Console	console.firebase.google.com	Web SDK config for Firestore JS	Instant — same Google account

12.2 Mumbai Hospital Reference (Simulator Seed)

Hospital	Lat	Lon	Type	Key specialties
KEM Hospital	19.0037	72.8424	Govt teaching	Neurosurgery, Trauma, Burns
Lokmanya Tilak General (Sion)	19.0411	72.8695	Govt teaching	Trauma, Burns, Ortho
Rajawadi Hospital	19.0853	72.9020	Govt district	General Surgery, Ortho
Bhabha Hospital	19.0612	72.8870	Govt district	Surgery, Paediatrics
Wockhardt Mulund	19.1626	72.9534	Private	Cardiology, Neurology
Kokilaben Ambani	19.1295	72.8259	Private	Neuro, Cardiac, Oncology

12.3 Local Start Commands

```bash
# Backend
cd rapid-backend
pip install -r requirements.txt
export GOOGLE_APPLICATION_CREDENTIALS=./credentials.json
uvicorn main:app --reload --port 8000

# Dashboard
cd rapid-dashboard && npm install && npm start
```

```
# Mobile
cd rapid-responder && npx expo start
# Change API_BASE to http://YOUR_LOCAL_IP:8000/api (not localhost)

# Test full flow
curl -X POST http://localhost:8000/api/incident -H 'Content-Type: application/json'
-d '{
  "incident_type": "road_accident",
  "crash_lat": 19.0728, "crash_lon": 72.8826,
  "patient_groups": [

{"severity":"critical","count":12,"injury_types":["head_trauma","internal_bleeding"
]},
    {"severity":"serious", "count":18,"injury_types":["fracture","burns"]},
    {"severity":"minor",   "count":10,"injury_types":["laceration"]}
  ],
  "reported_by": "Responder_01"
}'
```

12.4 Error Reference

Error	Cause	Fix
asyncio.TimeoutError in /incident	Gemini >8s — system should have fallen back	Check fallback_router was triggered: look for decision_path=FALLBACK in response
Gemini non-JSON response	Model prepended explanation despite JSON mode	raw.replace('```json',").replace('```',") before json.loads()
Vertex AI 403	Service account missing aiplatform.user	gcloud projects add-iam-policy-binding ... --role=roles/aiplatform.user
Overpass empty result	Hospital bbox too small or server overloaded	Increase radius; add retry; check adaptive radius is expanding
Firestore listener not firing	Realtime publication not enabled	Firebase Console → Firestore → check rules + publication settings
ORS ETAs all None	Coordinate order wrong — ORS uses [lon, lat]	In routing_ors.py: verify locations = [[crash_lon, crash_lat], ...]
ABDM 401	Token expired (25-min lifetime)	abdm.py caches token and refreshes before expiry — check cache logic
Expo app cannot reach backend	localhost is the container, not your machine	Use machine's LAN IP: http://192.168.x.x:8000/api — not localhost

Final note

> RAPID v4 is defined by three ideas: the system always routes (hybrid architecture with fallback), the system always explains (reason + confidence per decision), and the system always tells the truth about its data (provenance labels through to dashboard).
>
> Build the backend first. Get the /incident endpoint returning valid JSON from curl before you write any frontend code. Get the scoring engine working before you connect Gemini. Test the fallback before demo day. The demo is only as good as the system behind it.
>
> This is a proof-of-concept. Present it exactly as that — and what it proves is worth presenting.
